TRANSFORM is the result of an iterative process of co-creation involving experts and practitioners from southern and eastern Africa. This manual is based on a document prepared by Valentina Barca (Oxford Policy Management) and Richard Chirchir (Development Pathways), with contributions from Thibault Van Langenhove (ILO). It draws extensively from a publication on the topic of “Integrated Data and Information Management for Social Protection” published by the Australian Department of Foreign Affairs and Trade (DFAT) (Barca, 2017).

The editors of the TRANSFORM curriculum series are Luca Pellerano, Luis Frota and Nuno Cunha. Participants to workshops in Kenya, Zambia and Tanzania provided useful comments and inputs. The content of this manual does not reflect the official position of the different organizations supporting the TRANSFORM initiative.

TRANSFORM is a public good. All TRANSFORM materials including this manual are licensed under the Creative Commons Attribution-NonCommercial-ShareAlike 4.0 International Licence.

There is growing recognition that Management Information Systems, or MIS, play a pivotal role in the implementation of social protection (SP) schemes. In fact, programme MIS are increasingly viewed as a central plank that holds together social protection schemes’ core processes i.e. registration, determination of eligibility, payments, complaints & grievances, and monitoring and evaluation systems.

In recent years this interest has expanded to encompass a new focus on integrated approaches to data and information management, capable of assisting decision makers with more harmonized and systematic information across programmes to ensure coordinated responses to the multi-dimensional vulnerabilities of individuals across a life cycle, (UNICEF and World Bank, 2013).

This is in line with an increasing number of countries worldwide adopting national social protection strategies and implementing ILO Recommendation 202 (2012) concerning National Floors of Social Protection, seeking to coordinate interventions from different ministries and agencies (ILO 2015, Garcia and Moore, 2012, World Bank, 2015).

However, there is no widely acceptable terminology in the context of SP, especially when considering integrated approaches to data and information management. The tendency is to (Barca, 2017):

- Use the same terms referring to systems that vary depending on their objective, focus, functionality, maturity, sophistication and level of integration. For example, the acronym ‘MIS’ is used for systems that integrate data across several programs, as well as systems for individual programs.

- Use a variety of different terms when referring to systems that achieve broadly similar functions, with sometimes-different methods. The most common ‘synonyms’ are: Social Registry, Single Registry, Unified Database, Consolidated Database and Unified Registry.

All in all, countries have come up with their own definitions – all of which serve vary well to describe tailored country solutions, but none of which easily compare to experiences elsewhere in terms of defining core characteristics. This terminological confusion is also exacerbated by inadequate practical and detailed documentation on the subject. Quite often, this leads to: (i) confusion on the purpose, usage, objectives and evaluation of MIS in the SP sector; and (ii) mis-procurement, for example because suppliers may be biased towards a technical ICT based perspective, strictly packaging them in hardware and software terms with insufficient consideration for appropriateness and cost/benefit analysis and institutional matters. In addition to a lack of clear terminology, policy makers and technocrats also lack adequate information and knowledge on programme MIS and integrated approaches to information.
DEFINITIONS

2.1 OBJECTIVES

Having completed this section, the participant will gain an understanding of:

• The difference between a database, a registry, and an MIS
• The difference between a programme MIS and an integrated system for information management

There is no generally accepted terminology to describe data and information management in the context of SP. There are two main reasons for this confusion (Barca, 2017). First, the terms ‘database’, ‘registry’ and ‘MIS’ are often used interchangeably by social protection practitioners. However, these have different meanings and functions, as Box 1 clarifies. At both programme and integrated level, data and information management can only be achieved by combining the static ‘data repository’ role of a database/registry (effectively synonyms) with the dynamic ‘data interrogation’ role of an MIS.

Box 1: Database, Registry, MIS, Interoperability: definitions

This paper distinguishes between the following:

• Database – a system to organise, store and retrieve large amounts of data easily
• Register (nowadays referred to as registry) (a term of pre-ICT origin) – an official written record of names, events and/or transactions
• In a computerised environment, databases and ‘registries’ are overlapping concepts (effectively synonyms); both are for storing and retrieving data.
• MIS1 – a system that transforms retrieved data from a program’s database/register (or, in some cases, different databases linked to different modules) into information that can be used for efficient and effective program management.
• In social protection literature, the term MIS is associated with program-level information management. When discussing integrated solutions we use the general term ‘application software’ or ‘integrated MIS’, referring to the tailored solution that allows for the input, processing and output (e.g. display/presentation) of information.
• Interoperability: the ability of two or more systems (or components) to communicate by exchanging data, so the information is understood by the receiving agency and subsequently used for its own business purposes.

Source: Barca, 2017

Second, similar terms are used to refer to programme-specific and integrated approaches. For this paper, we introduce a new term to address this confusion:

• Integrated System for Information Management: refers to the broader system that enables the flow and management of information within the Social Protection sector and sometimes beyond, to other sectors. These are also sometimes referred to as ‘integrated social protection information systems’.

This is the area with the greatest confusion in the literature, primarily as integration of information management in the Social Protection sector can be achieved in different ways – influenced by the main objectives pursued with integration, and by a country’s context and trajectory.

In the following sections we first untangle the role of a programme level database and MIS (Section 3), then discuss approaches to integrating data across the sector to create an Integrated System for Information Management (Section 4). In either case, we invite readers never to trust the wording chosen by any given country to describe their data and information management solution, but to always question what that solution offers and what functions it performs. What matters is not the official name, but what the system is set up to do: most importantly where the data is flowing from (e.g. where is it originally being collected and what other data sources is it drawing from) and to (e.g. who has access to the data and how).

1 It should be noted that this term has been borrowed from the business world, where it is defined as a ‘system that provides information that organisations require to manage themselves efficiently and effectively’.
3

PROGRAMME MANAGEMENT INFORMATION SYSTEMS

3.1 OBJECTIVES

Having completed this section, the participant will gain an understanding of:

- The objectives and core functions supported by a programme MIS
- The key components of a functional programme MIS

3.2 OBJECTIVES AND FUNCTIONS SUPPORTED

A programme MIS enables the flow and management of information to support key processes within social protection schemes including:

- Identification and registration of applicants, using either a census or an on-demand method for data collection, see also MODULE S&I;
- Eligibility determination and enrolment (e.g., determining beneficiaries for the programme) – see also MODULE S&I and MODULE ADM;
- Continuous maintenance of Beneficiary Lists: e.g., removal of those no those who are no longer eligible
- Authentication and compliance monitoring (if applicable, e.g., when conditionality imposed) – see also MODULE ADM;
- Managing payments (e.g., producing “payrolls”, monitoring payment receipts, amounts paid, etc.) – see also MODULE ADM;
- Managing a grievance/ appeals and redress system – see also Module ADM;
- Managing on-going programme monitoring and evaluation (e.g., producing lists of beneficiaries who have enrolled, which benefits have been paid, level of payments, characteristics of beneficiaries, etc….) – see also MODULE M&E;
- Supporting on-going management and planning (e.g., notifying managers when a process should or has happened etc.) – see also MODULE M&E.

Ultimately, programme MISs enable harmonized implementation and monitoring of programmes, while ensuring transparency and good governance of Social Protection systems. In fact, several functionalities of modern social protection programmes – such as e-payments – cannot be set in place in the absence of a programme MIS.

Moreover, MIS depends critically on the quality of data on beneficiaries, and requires appropriate quality checks and controls. These can be performed by routine audits selecting random data or by statistical analysis of deviations on the lists of beneficiaries followed by qualitative in depth ‘spot checks’ of processes to determine the nature of the quality defaults. Weak or inaccurate information can result from weak controls resulting in inadequate information from the MIS (hence the popular adage ‘garbage in, garbage out’).

When putting in place MIS, it is important to be clear about the SP programme’s procedures, design parameters and operational processes from the outset. In fact, a programme MIS is a reflection of the operational manual of the programme, supported by appropriate technology. This implies that the MIS from one programme cannot be easily adapted for another programme, unless they have a very similar business process.

Conversely, not all programme functions are always supported by programme MIS, depending on programme objectives, set-up and what ‘Modules’ are prioritised during the MIS design. However, processes and procedures are fixed in time, as Box 2 below testifies. MIS can be adapted to follow changing programme requirements – e.g., increasingly moving core processes from a paper-based to an electronic platform – and are an important platform to support cost-effective programme expansion and a pre-requisite for cross-programme integration, as Section 1 further explores.

Box 2: LEAP’s evolving approach to registration and payments - Ghana

The Livelihood Empowerment Against Poverty (LEAP) programme, the flagship cash transfer programme in Ghana, initially relied on paperwork for the completion of its data collection questionnaire as well as for the recording of payments processed (beneficiaries confirmed receipt of the transfer via an intALLERY point on the hard copy of the payroll list. The data captured on the questionnaire was centrally entered into the database, the “poverty score” was calculated and eligibility determined. The MIS was used to electronically produce the payroll list before each payment. The Post Office used hard copies of the payroll list to deliver the payment in cash to the beneficiaries on previously announced paydays. On the basis of the hard copies, the Post Office then produced payment reports that summarized the information of the payments made (number of beneficiaries paid at each amount, payments paid etc.). Discussions are now underway to record the data electronically when registering potential beneficiaries and to introduce electronic payments:

- For data collection, this would require investing in hand-held devices and software that programme staff would use when conducting household interviews, and training the staff how to record the information. Data accuracy and speed of the overall process is expected to improve as a result.
- For electronic payments, LEAP is considering offering beneficiaries the choice between mobile phone payments or cash. For either, payment confirmation would be issued electronically, allowing for instantaneous update of the payment information in the database and fully automated compilation of payment reports.

2 A census method means that the programme attempts to visit all households to undertake targeting, an on-demand method means that applicants are expected to visit specific registration points to apply for the programme.
3.3 KEY COMPONENTS OF A FUNCTIONAL PROGRAMME MIS

Ultimately, a programme MIS is an application software that functions thanks to the interplay of several components that are tightly related (note that these apply to integrated systems too, see Section 1). We list and discuss these below, visualising their interplay in Figure 1 and further discussing good practices for each in Section 5.3 (Chirchir and Kidd, 2011 and Barca, 2017):

c. **Information requirements**: i.e. what data needs to be stored and managed. These are defined by programme staff on the basis of programme objectives and the core functions that need to be supported. For example, an MIS supporting a complaints and appeals process or a comprehensive M&E system will have additional information requirements compared to a programme that uses an MIS only for registration, enrolment and payment purposes.

d. **Software application (‘MIS’)**: as defined in Section 2 “Definitions” (above), the software application transforms the data that is retrieved from a programme’s database (or in some cases, different databases linked to different ‘modules’) into information that can be used for efficient and effective management. It can take many different forms depending on the information requirements and functions it is designed to perform (each operationalised within a different ‘module’). Such software can either be developed using proprietary applications or Open Source software.

e. **Database**: as defined in Section 2 “Definitions” (above). This is a system intended to easily organize, store, and retrieve large amounts of data. SP programmes can either use proprietary databases (Microsoft Access or Oracle) or Open Source.

f. **Hardware infrastructure**: this refers to the necessary infrastructure to securely collect and store large amounts of data (computers, PDAs, servers, etc.). Options for hardware technology vary, depending on the size of schemes, the overall context (remoteness, power supply, etc.), levels of security guaranteed and the particular operations to be undertaken.

g. **Telecommunications System**: this includes the network infrastructure – local area network and wide area network -that enables the necessary links between the software and the databases that feed into it. The choice of such system depends on local context (e.g. availability and reliability of internet).

Figure 1: Key components of a functional programme MIS

INTEGRATED SYSTEMS FOR INFORMATION MANAGEMENT

4.1 OBJECTIVES

Having completed this section, the participant will have an understanding of:

- The three main approaches to develop an integrated system for information management in the social protection sector.
- The advantages and risks of data and information integration in the Social Protection sector.
- What the main drivers of integration are and how these affect design choices.
- How country context affects design choices.

4.2 DEFINITIONS: THREE APPROACHES TO DEVELOPING AN INTEGRATED SYSTEM FOR INFORMATION MANAGEMENT

The word ‘single registry’ has gradually become the main word used by social protection policy-makers and practitioners to describe integrated approaches to data and information management in the social protection sector. This word is misleading, as box 3 explains, and the challenge of this paper is to unpack its meaning in different contexts.

Box 3: ‘Single registries’ – why is the word misleading?

Countries’ approaches to integrated data and information management in the social protection sector have often been referred to as ‘Single Registries’. Here, we explicitly choose to avoid the use of this terminology. Why?

- It was born as a literal translation of Brazil’s ‘Cadastro Unico’. In recent years Cadastro Unico is no longer translated as SingleRegistry but as Unified Registry.
- It has been used to refer to very different approaches to integration in different countries, so does not ensure clarity. Eg. Kenya’s solution is called a ‘Single Registry’ but has a different set-up and functionality compared to Brazil’s Cadastro Unico.
- Key stakeholders are rapidly moving away from the term (World Bank, ILO, etc.) – though it has stuck in describing country solutions to integration (e.g. Kenya).
- ‘Single registries’ are not necessarily ‘single’ since they often do not comprehend all social protection programs in a country and are not a substitute for individual MISs.
- ‘Single registries’ do not necessarily entail a ‘single’ process for targeting or unifying operations across programs.
- The word ‘registry’ alone does not cover the full functionality of data and information management in the social protection sector.

Source: Barca, 2017

Depending on country context and objectives pursued (see Section 1), there are two main approaches to developing a database/registry supporting an Integrated System for Information Management within the Social Protection sector. As defined within Barca, 2017, these are:

1. Integrated Beneficiary Registry: a database/registry which is created by integrating programme MISs of several different existing schemes, meaning integration is only achieved across data and information on beneficiaries (programme recipients). The main objective of such integration is to provide coordination and oversight (e.g. M&E) and integrate selected operations and services across programmes. In practice, Integrated Beneficiary Registries decentralise the process of data collection (individual programs are in charge of this) but centralise selected services by consolidating existing data. Examples include Kenya’s ‘Single Registry’, see Case Study, Mauritius and Seychelles.

2. Social Registry: a database/registry which collects and houses comprehensive (i.e. not program specific) information on potential beneficiaries within the country. In opposite fashion to integrated beneficiary registries, they front-end and centralise data integration by collecting data for a national database/register that is then drawn upon by specific programs4 (see Figure 2). Their primary function is to support and consolidate the initial social protection implementation phases of intake and registration. They can also support the assessment of needs and conditions for the purposes of determining potential eligibility for enrolment in selected social programs. Examples Brazil’s ‘Cadastro Unico’ and Indonesia’s ‘Unified Database’.

Note this is not necessarily the case, as data on applicants or anybody registered could also be integrated. But this case has not been encountered within country practice.

4 In our 2014 report, we discussed this in Section 2.3.2 as the ‘Centralised Model’ (Barca and Chirchir, 2014).
Box 4: Integrated beneficiary registry – what it is and is not

What it is:
- It is a registry of beneficiaries across several programs
- It integrates data from the program MISs of several programs, adopting a ‘service integration’ approach
- It supports integrated M&E and planning, and can be designed to support integration of delivery systems (e.g. payments and grievances)
- It is a building block that helps achieve integration. Its full potential as an ‘Information System’ is only unleashed when used together with a software application (‘Integrated MIS’) which enables dynamic links into other databases, systematically transforms data into information and analyses and uses the information.

What it is not:
- It is not necessarily comprehensive (i.e. ensuring 100 per cent coverage of population) as it only includes existing program beneficiaries.
- It cannot be used for ‘targeting’ or determination of (potential) eligibility for programs, because it only contains information on people or households who have already been deemed eligible by existing programs (beneficiaries and not potential beneficiaries).
- It does not necessarily include data from all social assistance programs in a country (some programs may not have been integrated).
- It does not necessarily include data from social insurance beneficiaries (as this data may not have been linked).
- It is not necessarily highly integrated with other government databases (e.g. civil registry, tax authority, etc.).
- It is not necessarily a substitute for individual program databases and MISs (unless specifically designed to do so, it cannot support program-specific delivery systems).
- It is not necessarily ‘national’ since social protection programs (and data collected for registration) are sometimes targeted geographically.

Source: Barca, 2017

---

Box 5: Social registry – what it is and is not

What it is:
- It is a registry/database of all people and households registered (the percentage of population registered will depend on the data collection approach and the user programme needs)
- Its primary function is to support the initial implementation phases of intake and registration, and assessment of needs and conditions for the purposes of determining potential eligibility for enrolment in selected social programs (‘targeting’)
- It aims to collect, record and store updated and historical information on individual and household characteristics and circumstances, and verifies and checks information consistency.
- It adopts a ‘data integration’ approach (through a shared master data system).
- It is a building block that helps achieve integration. Its full potential as an ‘Information System’ is only unleashed when used together with a software application which enables dynamic links to other databases, systematically transforms data into information and analyses and uses the information (see Section 4.5).

What it is not:
- It is not necessarily comprehensive (i.e. ensuring 100 per cent coverage of population) unless a national census survey is conducted covering the whole population.
- It is not just a list of beneficiaries (eligible people who have been selected for social protection programs) – i.e. it includes data on potential eligible households too.
- It does not necessarily enable an integrated overview of who is receiving what across different programs, as the main data flow is from the social registry to programme MISs, not back again.
- It does not necessarily provide data for all social assistance programs in a country (some programs may retain their own registration and data collection).
- It is not necessarily highly integrated with other government databases (e.g. civil registry, tax authority, etc).
- It does not necessarily offer a current snapshot of poverty, unless data is kept sufficiently up to date.
- It does not necessarily entail integrating operations across programs and is not a substitute for individual program registries and MISs.
- It is not necessarily ‘national’ since social protection programs (and therefore data collected by the social registry) are sometimes targeted geographically.

Source: Barca, 2017

---

1 For all the statements below where we state ‘not necessarily’ we mean this can be achieved if explicitly pursued.
2 It could be if 100% of the population were beneficiaries (e.g. universal guaranteed minimum income)
Box 6: Indonesia’s ‘Unified Database’, a Social Registry

Indonesia’s unified database (UDB) – the Basis Data Terpadu (BDT) – was designed to improve the targeting system of Indonesia’s main poverty alleviation programmes. The objective of establishing the registry was to reduce poverty targeting by 8-10% by 2014. The UDB now covers 24 million households (93 million individuals or 40 percent of population) located in over 77,000 villages nationwide – making it one of the largest databases in the world. The UDB data collection approach is a census survey of households pre-identified as poor, but the country may be moving towards an on-demand system. The database acts as a social registry and integrates data collection andeligibility determination across selected social assistance programs and community health insurance scheme, but data from these schemes is not shared back with UDB, so comprehensive overview of beneficiaries across programs is not possible. The UDB has also recently been integrated with the country’s national ID database, which is primarily used for data verification purposes.

Source: Barca, 2017

One technical approach to developing a social registry is to source data through interoperability of existing government databases: i.e. ensuring that these can ‘talk to each other’ (share data) effectively. We define this a ‘virtual’ social registry, an approach that can be used by countries wishing to have a comprehensive (100 per cent population), crosssector and proactive (linked to lifecycle events) overview of their population. The amount of information consolidated based on this virtual integration is sufficient to determine eligibility for universal social assistance programs, as for Argentina’s child allowance and Thailand’s health insurance beneficiary registry schemes (see Box 7), but not for poverty-targeted programs. When this is the case, information from several sources is consolidated and further data is then collected in order to determine (targeted) eligibility into social programs (Barca, 2017).

Box 7: Thailand’s national health insurance registry: a virtual social registry

• Built on a partnership between Thailand’s Ministry of Interior and social health protection schemes, the country’s national health insurance beneficiary registry facilitates access to health care for all.
• Launched in 2001, the Universal Coverage Scheme (UCS) covers the 76 per cent of the population who are not covered by existing social health protection schemes. UCS beneficiaries are identified by extracting data from the national population database maintained by the Ministry of Interior and – using the country’s 13-digit national ID number* as a ‘unique ID’ (see also Section 4.7.1) – removing individuals who already benefit from other schemes. The National Health Security Office – an autonomous institution – was created and designated to compile and maintain the resulting registry.
• Beyond helping to verify eligibility, the national ID number is also used by health-care providers to track delivered services, settle claims, and build a shared medical record for each patient.

4.3 HOW THESE APPROACHES RELATE TO EACH OTHER

As briefly mentioned above, these approaches to developing an Integrated System for Information Management within the Social Protection sector are not mutually exclusive, and can evolve over time. For example, country consolidating information from existing programs using an integrated beneficiary registry approach may decide to coordinate data collection activities and move towards a social registry approach. This approach may then increase its level of interoperability with other government databases and take on features of a virtual social registry, as has been the case in Chile, where the majority of data for the ‘Registro Social de Hogares’ is now sourced through existing administrative databases.

• High levels of interoperability can be achieved within all of the three approaches.

The different development of integrated beneficiary registries, social registries and virtual social registries are represented visually in Figure 2.

Figure 2: Integrated beneficiary registry, social registry and virtual social registry

*This unique 13-digit identification number is generated for each Thai citizen at the time their birth is registered in the national civil registration database. National ID cards are issued to citizens when they reach seven years of age. Non-Thai residents and foreigners can also be issued with ad hoc ID numbers.

*Available at socialprotection.org
Moreover, the extent and type of integration ultimately achieved depends on the number and type of linkages established with other databases - see the Table below for important examples.

Table 1: What type of integration can be achieved? Comparing Social Registries, Integrated Beneficiary Registries and Virtual Social Registries

Box 8: Comparison to a country’s population

- To better understand the relationship between social registries, integrated beneficiary registries and virtual social registries, it can be useful to represent them against the wider population (which can be potentially reached by virtual social registries). In Figure 3:
  - The widest red circle is a country’s whole population (rich and poor). Any interoperable system ensuring the creation of a virtual social registry could potentially reach 100 per cent of this population by linking to a country’s national ID and/or civil registry
  - The next blue circle is the population included in a country’s social registry. This is 100 per cent of the total population in a few cases (red and blue circles overlap) – notably where comprehensive census surveys are completed – but most often focuses on the sub-population of those who are relatively poorer and primarily eligible for means-tested social assistance programs
  - The smallest green circle represents the population included in a country’s integrated beneficiary registry: the sum of all the beneficiaries of the social protection programs whose MISs have been integrated
  - The grey dotted circle represents a country’s eligible population (those who are entitled to receive some form of social assistance benefit based on the targeting criteria of any of the existing programs). The area that does not overlap with the green or the blue line represents households who should be included but are not (exclusion errors). The area within the blue circle that does not overlap with the grey one represents households who are included in the social registry but not eligible based on existing eligibility criteria (they could be if these changed). All beneficiary households (green circle) are eligible (unless there are inclusion errors, not figured here).

Figure 3: How social registries and integrated beneficiary registries compare to a country’s total and eligible population

Source: Barca, 2017

In cases of universal coverage, this grey dotted line would correspond to the outer red circle.
4.4 ADVANTAGES AND RISKS OF DATA AND INFORMATION INTEGRATION

Integration of information and data within the SP sector can bring policy and operational gains. As discussed within Barca, 2017, from a policy perspective, advantages could include the ability to:

- apply a potentially more equitable approach to distributing resources based on objective and comparable information, addressing the uneven and unequal provision of social protection across social groups and administrative jurisdictions
- increase responsiveness and inclusiveness of interventions to serve the chronically poor, serve those structurally vulnerable to poverty and respond to individual shocks, such as job loss, disability, childbirth, old age, or large crises (for example, natural disasters or conflict)
- ensure universal coverage and support implementation of the Social Protection Floor, potentially coordinating social assistance and social insurance
- build a stronger link to complementary institutional frameworks and wider social and economic policies\textsuperscript{11}
- increase transparency and accountability, since program information can be more easily shared and compared
- improve the “image” of the social protection system, as citizens better understand their entitlements
- increase knowledge on poverty and vulnerability based on access to the large amount of information available.

From an operational perspective, advantages include the ability to:

- facilitate oversight of multiple schemes and report to policymakers
- improve budget planning and ability to model and test policy changes
- decrease the burden on staff (e.g. less paperwork, less manual reporting, etc.)
- decrease the burden on potential applicants (e.g. can apply for several programmes at once, less documents needed, better/coordinates information on entitlements
- avoid duplication of effort (for example, with data collection activities) and potentially establish a ‘common entry point’ for social protection
- establish common systems across all schemes (e.g. payment system, grievance mechanisms, etc.), increasing efficiency and saving money
- better manage error and fraud and monitor multiple payments (keeping track of who is receiving what)
- further digitalise service delivery, potentially reaching out to citizens in new ways (e.g. mobile phones)
- ensure reinforcing measures and/or complementary interventions to multiple disadvantaged households
- enable beneficiaries to transition between schemes as their circumstances change

4.5 SET-UP FOR ‘FULL’ INTEGRATION

Potentially, the greater the interconnectivity, the greater are the gains in efficiency and effectiveness of service delivery. The key issue is therefore the level of coordination and interoperability\textsuperscript{12} achieved, not the creation of a super-sized system or database that serves all purposes.\textsuperscript{12} It does not matter whether the system is set-up as a ‘Social Registry’, ‘Integrated Beneficiary Registry’ or ‘Virtual Social Registry’ - what matters is that the approach chosen:

- responds to a country’s needs (see Section 4.6),
- is appropriate to its context (see Section 4.7) and
- is affordable and sustainable (see Section 5)

A system that guarantees full integration within the Social Protection sector and beyond, in accordance with the right to privacy, would ensure the application software (‘Integrated MIS’) establishes a direct (e.g. web service) link to:

- All Social Assistance Programme MISs and related databases: to keep track of who is receiving what, potentially integrate selected services, and enable adequate M&E and planning

\textsuperscript{11} SP systems have the potential for maximizing outcomes and impacts if they are conceived as integral components of national development and poverty reduction strategies, linked with complementary programmes (e.g., food aid promotion, labour market and intermediation programmes, food security programmes, etc.) and macro-policy determinants (macroeconomic stability, economic growth, etc.). Organisation for Economic Co-operation and Development (OECD), 2009.

\textsuperscript{12} Interoperability is a characteristic of a product or system, whose interfaces are completely understood, to work with other producer systems, present or future, in either implementation or access, without any restrictions.

\textsuperscript{13} A large whole-of-government information and communications technology system is unrealistic and risks being too complex to be useful. Instead, e-government, for the purposes of this paper, means a set of policies and frameworks that ensure interoperability of multiple government sector systems and use of IT to provide services to citizens.
4.6 POLICY OBJECTIVES: INTEGRATING - WHAT AND WHY?

It is evident that integration is mainly a policy issue requiring political and institutional arrangements before technical considerations, meaning that effective systems for data and information management cannot operate in a policy/ institutional and programmatic vacuum. In this section we outline the three main and overlapping objectives pursued by policy-makers aiming to achieve integration, and the approaches to integration that can support these Barca, 2017.

1. Providing oversight: Integrating to have an overview of who is receiving what, coordinating interventions, facilitating planning and more generally providing combined monitoring and evaluation (M&E) across programs. Ex. Kenya National Safety Net Single Registry.
   - Achievable through a) An integrated Beneficiary Registry; b) A Social Registry or Virtual Social Registry which exchanges data with Programme MISs (often not the case)
2. Consolidation of targeting processes so they serve multiple social programs. The rationale here is to avoid the use of different and possibly conflicting targeting methods, increasing scale and thus cost efficiency of targeting tools. The aim is to create and maintain a database of poor households, which can be used for targeting of new programs.
   - Achievable through: a) A Social Registry; b) A Virtual Social Registry with no additional data collection (only universal non-means tested programmes); c) A Virtual Social Registry with additional data collection
3. Integrating data management to integrate operations and services. This is in line with the concept of the Single Window Services within the social protection sector and beyond.
   - Achievable through (when this is a policy objective): a) An Integrated Beneficiary Registry; b) A Social Registry or Virtual Social Registry which exchanges data with Programme MISs (often not the case)

Below, we briefly outline key considerations that need to be made when attempting to achieve either or multiple of these objectives.

4.6.1 Integration for oversight, coordination and planning and M&E

As shown above, only when data is shared back from individual programme MIS to the national Registry (always the case for Integrated Beneficiary Registries, but often not the case for Social Registries or Virtual Registries) it is possible to provide an integrated overview of programme beneficiaries to understand who is receiving what and feed into Social Protection policy planning.

However, this requirement alone is not sufficient. Even complete, high-quality data have no value unless they can be converted into information that is useful for making decisions and improving programs (Villalobos et al, 2010) and policy. Whatever the integration set-up, effective systems for the on-going analysis and use of existing data also need to be developed. Good practice to ensure adequate reporting and use of data across government include (OPM, 2015):

a. Clearly identifying data needs and reporting requirements of each actor and catering to those within an overarching M&E framework

b. Developing a relevant and timely reporting system (e.g. Module within the integrated MIS), informed by constant testing by data users. See for example Kenya’s online Single Registry (Figure 9 in Case Study)

c. Providing adequately disaggregated data, catering to the planning needs of local governments and other data users. This is critical if we want local governments to be supportive of the system, which means analysis of the data needs at the local level.
d. Presenting reports in easy to read formats e.g. dashboards, charts and graphs

e. Using GIS and geo-referenced data where possible (e.g. Uruguay, Indonesia, Chile, Brazil, etc.)
f. Publishing aggregate key data trends on a relevant institutional website, to engage citizenship more widely (e.g. Indonesia, Kenya)
g. Encouraging data-sharing with a wide range of actors, including research institutions and universities

Figure 4: An example of Chile’s geo-referenced reporting system

4.6.2 Integration for consolidated targeting

One of the primary roles of social registries (as opposed to integrated beneficiary registries — see above) is to support the gateway phases of intake/registration and determination of eligibility across social sector programs. Many social registries score or rank households registered based on their levels of poverty and vulnerability at central level, to avoid political interference. The outcome is a compiled list of potentially eligible households or a ranked list of all households. This output can then be shared with individual program implementers or decentralised counterparts, who use the national list as a basis for eligibility determination and often adapt it to their purposes by (Barca, 2017):

b. adding further criteria: for example, pregnant women or people aged 65 and over

b. validating lists provided: for example, publicising the list in the community and giving 30 days for people to object, calling a community meeting or conducting household visits

c. choosing what percentage of households ranked nationally are to be included: for example, only the poorest 10 per cent.

This two-tiered targeting approach enables a common methodology to be developed across programs while maintaining the flexibility needed by individual programs or decentralised units of government to target specific household types.

• Social Insurance MISs and related databases: to integrate social assistance and social insurance and ensure a lifecycle and comprehensive approach to Social Protection

• Any other relevant Government MISs and related databases (e.g. Civil Registry, Tax Authority, etc.): to collect and cross-check data, enhance accountability, and enable a comprehensive approach to Social Policy planning.

This can most robustly be achieved using each citizen’s National ID number as a unique identifier (see Section 4.7.1 for more details and critique), allowing for instant access for more up-to-date data, with information flowing in both directions – conditional on the permission-level of each user.
In other cases the full dataset from the social registry is shared with user programmes, meaning the social registry only integrates intake/registration, not eligibility determination. However, the risks an integrated approach to intake/registration and/or determining eligibility poses go beyond those faced by individual social protection programs, as any mistake can lead to exclusion from multiple social sector schemes.

For example, integrated intake/registration could lead to systematic exclusion of certain households because of problems with:

- data collection: e.g. low take-up for on-demand systems, biased coverage for census survey systems, political interference at local level
- data/administrative requirements: e.g. lack of an ID card

An integrated process for determining eligibility could similarly be problematic if the eligibility formula does not accurately capture those in need or if the national approach to determining eligibility does not adequately reflect local poverty profiles – a big challenge in large and diverse countries (e.g. Indonesia, Brazil).

Approaches used to mitigate these risks have included (OPM 2015):

a. institutionalising a validation process within communities, at registration. However this is time-consuming and can be counterproductive if validation results are not integrated into the system
b. enabling two decision-making layers. In Turkey, for example, data determines eligibility but human decision (following household visit) prevails. Central level then validates local decisions, performing spot-checks on discrepancies with the central targeting index
c. having in place a functional grievance mechanism for complaints and appeals, e.g. a toll-free line (problematic if this does not translate into changes in targeting decisions)
d. ensuring, through tailored communication strategies, that people understand targeting (e.g. to increase take-up and registration).
e. including parameters relating to local context (urban/rural, services available etc.), as is done by SISBEN in Colombia.

4.6.3 Integrated management of selected operations and services

One of the ultimate aims of integration of data and information management should be to improve citizen’s experience and access to social protection programmes. However, integrating operations and services across the social protection spectrum requires very high levels of capacity and institutional coordination – and may not always be feasible. For example, individual programs may be reluctant to relinquish control over their operations. In this section we briefly discuss the key operations – beyond determination of eligibility – that could usefully be integrated and managed nationally. See also Modules S&I and Admin

- Communications – Adopting an integrated approach to social protection entails providing clear, transparent and non-contradictory information to citizens on their rights and responsibilities in relation to the services they may or may not be entitled to. An Integrated System for Information Management could potentially aid this process by rationalising access to and receipt of social programs: ensuring one point of contact and source of information.

- Registration – Integrating the approach to registering potential beneficiaries of social protection programs – as is the case for Social Registries with ongoing on-demand registration – can have large impacts on citizens (ensuring ease of access, applicants can apply for several programmes at once, less documents needed, better/coordinated information on entitlements, etc.) This is in line with best practice advocated by the ILO in developing Single Window Services. See also comments above.

- Updating registration information for on-going assessment of eligibility – a key area where integration could generate benefits for the administration of social protection programs is the possibility of continuously updating citizen’s registration information. This would allow the system to continuously re-assess eligibility for a wide range of programs, especially universal categorical ones. For example, by crosschecking information from the social security system and Civil Registry, the system could flag households eligible for child benefits, pensions or unemployment insurance. This would enable a government to provide immediate protection when needs arise, but also to ‘exit’ households who are no longer eligible (age cut-offs, death, etc.). Countries moving in this direction include Mauritius, with its twinned Single Registry, Argentina, Chile and Uganda.

- Payments (where relevant, e.g. cash transfers) – Integrating payments can be difficult where existing programs have different payment mechanisms and providers (e.g. banks, post offices, private agencies and manual mechanisms such as armed vehicles). However, Brazil, Turkey and Chile show that this level of integration is possible where adequate coordination is in place and the integrated MIS is linked to the payment service provider. For example, in Kenya such integration is increasingly in place thanks to the role of Equity Bank and Kenya Commercial Bank, and to a 2013 presidential directive mandating the digitisation of all government payments. For example, the country’s ‘Single Registry’ now supports the verification of the beneficiary list through pre-payroll and post-payroll checks (Mwaisaij, 2016).

- M&E systems – see Section 4.6.1

- Grievance mechanisms – there could be economies of scope and scale, and benefits in terms of transparency and ease of access, integrating the overarching grievance procedure (e.g. setting up a national hotline that redirects programme specific queries, while also using a highly trained network of staff at local level as first points of access). Several countries are moving in this direction (e.g. Indonesia, Kenya), but not enough evidence is available to date. In South Africa, the experience of the Social security tribunal was to operate a culture shift from previously decentralized social assistance to a more rules based eligibility criteria – it served to inform people about the new eligibility rules – the SOC PEN system was instrumental in helping quickly determine eligibility and inform about participants why they did not qualify etc but this supposes rules are transparent and comprehensible.

- Case Management – Each beneficiary accessing a social protection programme comes with a particular history and set of needs, which are not, necessarily all addressed through standard programme operations. An integrated Social Protection Case Management System would follow each individual ‘case’, ensuring that people’s needs (children, disabled people, the elderly, vulnerable households, etc.) are assessed on a continuous basis and addressed: a) within existing programmes (e.g. providing guidance, information, support), and b) by linking beneficiaries to a wider set of complementary services available within the country (through some form of a Referral System).

- Conditionalities – In theory, full integration could make it more efficient to monitor conditionality. For example, connecting the Education Ministry MIS to the Integrated MIS could provide timely data on attendance. This is a highly complex process from an institutional and data management point of view, which is why only Turkey has succeeded in making this process entirely virtual – standard practice is to adopt batch-sending processes.

A great example of a legacy system being used to manage a wide variety of grants through an integrated system for data and information management is South Africa (see Box 9).
The Republic of South Africa’s Department of Social Development (established in 1929), together with the South Africa Social Security Agency (SASSA), runs a comprehensive system of social assistance grants and processes 16,991,634 grants monthly14 (collected by just over 11 million recipients). The grants are processed using a legacy system called SOCPEN, which started in the 1930s. SOCPEN runs on a non-graphical user interface based on mainframes located at the State Information Technology Agency (SITA). Its legacy enterprise database, Adisas, manages more than 2,300 concurrent users and has a register of more than 1.6 million beneficiaries, with primary data collected through an on-demand application system. Since social security implementation is handled by one agency, it can be argued that South Africa operates a ‘singlewindow’ for processing applicants.

To perform its key functions – processing applications for the country’s six social grants, determining beneficiaries from the list of applicants, maintaining the payroll for the grants,15 and automatically producing a list of beneficiaries to be reassessed – SOCPEN links to a file-tracking system providing real-time information on the status of social grant applications and to Livelink, a document management system that scans and manages records of grant recipients.

SOCPEN interfaces with other government MISs, the most important of which is that of the Department of Home Affairs, and can provide real-time information from the population register (e.g. deaths). An online interface has also been established with PERSAL (government payroll system) to crosscheck income data. Other ad hoc data sources (not linked online) include the Unemployment Insurance Fund, Government Employees Pension Fund, payroll system of the Defence Force, National Treasury (to verify beneficiary banking details); Department of Basic Education learner database; and special investigations unit (to identify fraudulent grants).

- While proving that legacy systems can be very effective, the system has limits:
  - reaching its ability to be customised and being overtaken by many technological changes
  - producing substantial volumes of paperwork
  - not being an organisation-wide system covering all SASSA operations, leading to duplication of datastoring and making M&E more difficult
  - linking with other MISs but not always in real time
  - focusing on managing operational processes for grant delivery rather than on policy coordination and oversight.

Moreover, approaches to further integrate SOCPEN and move towards a national integrated social information system (NISIS) have failed to date.16

Table 2: Key enablers for the development of an Integrated System for Information Management

<table>
<thead>
<tr>
<th>MANAGEMENT INFORMATION SYSTEMS &amp; APPROACHES TO DATA INTEGRATION</th>
</tr>
</thead>
<tbody>
<tr>
<td>4.7 COUNTRY CONTEXT: INTEGRATING HOW?</td>
</tr>
</tbody>
</table>

Beyond policy objectives, it is clear that certain set-ups for integration will only be achievable in certain contexts: a country’s historical trajectory and ultimate ‘endowment’ has a great weight in determining choices. We discuss key enablers below (noting that recommendation in Section 3.3 also apply and that the key questions for a needs and feasibility assessment are set-out in Section 5.2).

<table>
<thead>
<tr>
<th>DIMENSION</th>
<th>WHEN IS THE DEVELOPMENT OF AN INTEGRATED SYSTEM FOR INFORMATION MANAGEMENT FOR SOCIAL PROTECTION FEASIBLE? KEY ISSUES</th>
</tr>
</thead>
</table>
| Policy environment and budget | • National policy focused on developing a systems approach to social protection (aiming to achieve coordination and harmonisation to fill coverage gaps and address the fragmentation that limits the effectiveness and impact of social protection policies and programs)
• Integration of data and information management clearly articulated in National Development Plans, National Social Protection Policies and Strategies, and other strategic documents
• Strong political leadership advocating for reform and coordinating institutional actors
• Focus on ensuring political buy-in and ownership of all actors, including social partners and representatives of beneficiaries, by addressing advantages for each (e.g. through social dialogue, participatory planning process and stakeholder mapping)
• Existence of Programme operational rules and guidelines (often ICTs prompt the need to clarify this beforehand!)
• Sufficient capacity to identify and cost policy options, assess affordability and identify available financing options
• Budget availability (and policy support) to back the vision
• Acceptance of slow, iterative process and failures |
| Staff availability and capacity | • Highly trained and qualified staff, motivated through a performance management system, and at a sufficiently high salary to guarantee retention – both at central and local level
• Sufficient budget for continuous staff training and retention
• Culture of sharing and problem solving, e.g. no resistance and complacency of staff to want to keep the system as it is
• Presence of ‘hybrid’ staff that understand both context, organization, and work processes of their sector and the role of information system |
| Governance and institutional structure | • Existence or easy creation of an independent unit that is in charge of managing and maintaining the new system at a sufficiently high government level to effectively coordinate with all stakeholders and update new regulations etc.
• Role of the Integrated System for Information Management and its managing unit embedded in legislation (example Brazil)
• Potential for strong institutional ties with other government bodies
• Absence of parallel or competing structures for oversight of social protection policy (no power struggles); levels of agreement on basic issues regarding payment systems/contract and compensation of administration costs between agencies, etc.
• Stakeholders clearly identified and their roles formalised through legally binding agreements, carefully designed incentives and mutually agreed terms of reference
• Decentralisation approached as a resource rather than impediment: providing added value to decentralised government (tailored functionality and data sharing), involving local government and creating performance incentives |

When attempting to integrate programs across and outside the social protection sector, a unique ID number for individuals is needed to link Registry information with other systems and programs. The most easy and effective solution for this – though not free of controversy (see Table 3) – is the use of a country’s National ID number.

4.7.1 Lack of national unique number identifier (e.g. ID)

When attempting to integrate programs across and outside the social protection sector, a unique ID number for individuals is needed to link Registry information with other systems and programs. The most easy and effective solution for this – though not free of controversy (see Table 3) – is the use of a country’s National ID number.

OPPORTUNITIES

- Enables instant integration of different programs and sectoral databases (acts as unique identifier), potentially improving service delivery
- Can provide online, cost-effective, ubiquitous authentication services across a country: e.g. for data verification (ensuring uniqueness – 1:n – and identity – 1:1)
- Can act as a data-source, with information on all citizens (e.g., names, addresses, etc.), thus helping to identify vulnerable groups or persons
- Facilitates an audit trail down to the recipient of social assistance thus increasing transparency and accountability while reducing program leakages and fraud
- Can complement financial inclusion initiatives and enable access to and reduce the costs of financial services: e.g. enables e-payments to beneficiaries (fulfills Know Your Customer Requirements)
- Can support integration of payment systems and other services across programmes

CHALLENGES AND RISKS

- Few lower and middle income countries have 100% population coverage within their Civil Registry
- The most vulnerable and disadvantaged individuals are often those without a national ID (because of lack of information and direct (e.g. fees), indirect (e.g. transport) and opportunity costs (time).
- Certain categories of population could be systematically excluded from the National ID and therefore Social Protection provision: most importantly non-citizens, migrants, indigenous people and minors (e.g. street children)
- Risky in contexts with no legal framework for privacy and where governance is poor – privacy concerns, while perhaps not manifested initially, will likely increase over time
- ID projects can have large initial capital costs, not justified by needs in terms of Social Protection provision
- Where biometrics involved, needs ad-hoc approach for categories that cannot be easily registered (e.g. fingerprints for very young and very old)

Many countries, however, do not have a National ID number or have insufficient coverage of the poorest and most vulnerable population groups. So how to ensure linkage of databases in the lack of an existing ID system and unique identifier? Country experience suggests the following avenues (Barca, 2017; Castaneda and Lindert 2005; Gelb and Clark 2012; Gelb 2014):

- Building a business case for a National ID System as an important pillar for delivery of social services, working alongside national registry offices on a common effort to register individuals particularly in remote or poor areas where lack of identity documentation and numbers is prevalent. For example, this could include:

1. Assessing the effectiveness of a National ID system, evaluating pros and cons (see for example Table 3 and investing in a feasibility study as part of data and information integration planning). Estimates on costs of large ID programs run from $3 to $15 per head.

Source: Barca, 2017

Table 3: The opportunities and challenges of linking a National ID number to Social Protection provision

Source: Adapted by Barca, 2017 from Gelb and Clark 2012. Note that many of the ‘opportunities’ could also be guaranteed by other robust ID systems.
2. Incorporating civil registration as a key objective of a social protection program. Examples include Kenya’s Cash Transfer for Orphans and Vulnerable Children cash transfer, Kenya’s Hunger Safety Net Program and Uganda’s Social Assistance Grants for Empowerment program, where beneficiary households are given easy access to national ID24;  
3. Registering households for National ID during registration for the Social Registry. In Lesotho, for example, this was done during registration for the Child Grant Programme.  
   - Incorporating social protection as a key objective of civil registration and National ID efforts. This is the case in Pakistan and India. Partner with Home affairs for national campaign and extension of ID registration  
   1. Taking advantage of national events such as elections to register all citizens. This has been done in Bangladesh, Benin and DRC, for example;  
   2. Sharing costs of setting up an ID system among government agencies to justify investment;  
   3. Linking the ID to other desirable services. For example as part of the rollout of comprehensive ID system called “Adhaar”23, India’s government is opening bank accounts. In Pakistan, NADRA achieved registration by promoting wide range of wider benefits (ability to perform hajj pilgrimage, access to bank accounts and other services).  
   - Considering the relative effectiveness of other existing functional ID systems e.g. Voter Registration, Birth Registration, etc.  
   - Generating another functional ‘unique number’ to substitute a national ID number and complement existing functional IDs. The most famous is the US’s Social Security Number; a strategy adopted in Brazil22, Mauritius, and Mexico, for example. However, the common practice of assigning new numbers as people apply (new number for each questionnaire) could lead to potential problems with duplication, as in Colombia.  
   - Designing formulae or “algorithms” that combine a number of variables to create a comparable identifier across databases in the government sector. For example, Brazil’s “match key” variables consist of name, mother’s name, birth and codes from selected documents21, while in the Philippines probability models for matching data are based on birth dates and other identifying data;  
   - Rejecting those who do not have an ID number, as Brazil did, for example, in the early phases of the Cadastro Único. However, this is not a viable strategy for an inclusive Registry.  

4.7.2 Lack of appropriate safeguards to ensure data security and privacy  
Eligibility into social protection programmes requires substantial amounts of personal information to be gathered from potential beneficiaries, including sensitive data on health, income, assets, and housing. This poses the risk of misusing or losing such information,21 potentially exposing households to further vulnerability (CALP 2013; Hosein and Nyst 2013; ASPP 2015). In integrated systems, this risk increases, especially as data is shared across multiple actors. Importantly, the right to information privacy is also embedded in the Universal Declaration of Human Rights (UDHR), the International Covenant on Civil and Political Rights29 and the ILO Social Protection Floors Recommendation, 2012 (No. 202), which explicitly calls on States to “establish a legal framework to secure and protect private individual information in their social security data systems” (para, 23)30.  

Best practice shows that – where Social Registries or any level of Interoperability is being developed – country laws should adhere to international data transfer and information privacy protocols, which legislate the collection, transfer and storage of information. This becomes even more important where data is shared across a public network and several institutions.

INTEGRATED SYSTEMS FOR INFORMATION MANAGEMENT  
Key laws that should be adhered to include: Council of Europe’s Convention for the Protection of Individuals with regard to Automatic Processing of Personal Data; United Nations Guidelines for the Regulation of Computerized Personal Data Files; and OECD Guidelines on the Protection of Privacy and Trans-border Flows of Personal Data. Such practice is common, for example, in all Latin American countries.  
In particular, some of the most important principles and actions for the secure use of personal data within social protection programmes are summarised below (CALP, 2013; Barca, 2017):  
1. ensure informed consent of those who are sharing their data, explaining the nature of the data being collected, the purpose of collection, with whom it will be shared, and who is responsible for the secure use of their data;29  
2. establish a mechanism to respond to any complaints or concerns citizens may have about the use of their personal data;  
3. regularly undergo information system audits to analyse, document and understand the flow of data and develop risk mitigation strategies for potential risks arising from these flows;  
4. implement appropriate technical and operational security standards for each stage of the collection, use and transfer of beneficiary data to prevent unauthorised access, disclosure or loss;  
5. implement appropriate mechanisms to provide individuals with the right to access their personal data and correct it  
6. ensure data back-up and protection protocols and guidelines, for example by:  
   - ensuring data users are trained and aware of these issues;  
   - implementing user profiles on information system access, allowing for an audit trail  
   - sharing data in anonymised and summary format except when needed  
   - establishing non-disclosure agreements for anyone who is granted access to data;  

Specifically, backup and security should conform to ISO 27001—an approach to managing confidential or sensitive information—so it remains secure, confidential and with its integrity intact. In some pilot transfer programs (for example, the Hunger Safety Net Programme Kenya and Social Assistance Grants for Empowerment in Uganda) backup and security systems are hosted in physically and logically secured servers at program level. But national programs sometimes outsource this security and hosting function. In Pakistan, for example, the Benazir Income Support Programme database is hosted by the National Database and Registration Authority. In South Africa, SOCPEN is hosted by the South African Information Technology Agency (SIITA).  
A trade-off emerges when the need for data privacy conflicts with transparency and accountability. Several countries have solved this by making certain aggregate and anonymised datasets and data visualisations available to the general public. In Indonesia, for example, 16 of the 40 core indicators in the Social Registry are available online in aggregate format.

4.8 COUNTRY EXPERIENCES TO DATE  
Support for integrated data and information management for social protection has grown considerably in the last 20 years especially. The early wave goes back to the late 70s and early 80s, when Chile and South Africa were starting to set up their systems (see Box 9 for South Africa’s legacy system). Based on data in the World Bank’s State of Social Safety Nets 2015 (Honorati, Gentilini and Yemtov, 2015) and on our updated assessment, integrated data and information management for social protection is already fully institutionalised in 30 low- and middle-income countries worldwide (15 in Latin America, six in Africa, five in Europe and the Middle East) across the Asia-Pacific.31 Many of these systems are set up as social registries. Currently the number of countries considering and developing options for integration in this sector is expanding rapidly, with an additional 31 countries – 18 of which are in Sub-Saharan Africa – in the process of developing an integrated system for information management (see Table 4 overleaf).

---
21 A controversial example comes from the Dominican Republic, where a program aiming to register poor citizens de facto stripped citizenship rights from many residents of Haitian extraction – see here.
22 See for example Brazil’s ‘Social identification number’ (unique number for each registered person).
23 See here.
24 Note that cross-checks among databases using these algorithms as a ‘Unique ID’ are not 100% accurate.
25 For example, data might be likely used for blackmail, identity theft or, marketing purposes.
26 Article 17 of the Convention provides that “No one shall be subjected to arbitrary or unlawful interference with his privacy, family, home or correspondence, nor to unlawful attacks on his honour and reputation”  
27 States that are party to other United Nations or regional instruments, such as the International Covenant on Civil and Political Rights, the American Convention on Human Rights, or the African Union Principles on Freedom of Expression should also take into account their international obligations in the implementation of the national social protection floors.
28 Recent research in Kenya showed that this was often not the case (ASPP 2015).
29 See CG/EC 27001:2013 is an information security standard that was published in September 2013. It is published by the International Organisation for Standardisation (ISO) and the International Electrotechnical Commission (IEC). Organisations which meet the standard may be certified complaint by an independent third party.
30 The World Bank’s full list includes 21 countries. We have added four cases based on an updated assessment.

Source: Honorati, Gentilini and Yemtsov (2015) and authors’ integrations.

These integrated systems range greatly in their set-up, functions and levels of cross-sectoral integration. This is exemplified by the number of social protection programs they serve, which ranges from two (Cabo Verde) to over 80 (Chile), as shown in figure 5 below, and by the number of web service links they establish with other government databases, which ranges from zero to 43 (Chile). Of course, they also differ in their approach to integration – many are operationalised as social registries, others as integrated beneficiary registries and others as virtual social registries30.

30The amount of information available on each country’s experience was not sufficient to classify these explicitly.
Moreover, whether calculated as numbers of individuals or households or as a percentage of population, the size of existing integrated systems for information management (i.e. the total number of households and individuals they have data on) varies greatly from country to country, depending on a variety of factors.

As exemplified in Figure 6 the highest population ‘coverage’ (percentage of population registered) is reached by systems that guarantee full interoperability. For example, in Uruguay the use of data from existing administrative databases (using national ID for linking) means all citizens and residents are registered (including those who have died, those who have moved abroad and foreigners living in the country). Social registries with census survey approaches to data collection that aim to survey all households in a given country follow close behind – as exemplified by Pakistan and the Philippines. Countries with on-demand data collection approaches (e.g. Brazil and South Africa) or census-surveys of selected population groups (e.g. Indonesia) have marginally lower coverage rates – 40–50 per cent of the population. By definition, countries with integrated beneficiary registries have the lowest coverage, as only beneficiaries are included in the integrated registry (e.g. Kenya). Djibouti and Malaysia fail to hit the 5 per cent coverage mark as their systems are currently being expanded. (Barca, 2017)

Source: authors’ analysis (online survey and recent literature). Note: Countries and registries included are not necessarily the same as above, as some report number of households and some report number of individuals.
Less significant as a comparison (as it is strongly affected by a country’s population size), yet interesting to give a sense of the magnitude of these efforts is the number of households registered (see Figure 7: Number of households registered, selected registries). The largest of all efforts in absolute terms is Pakistan’s National Socio-Economic Registry (linked to BISP), which contains information on 167 million individuals, equivalent to 27 million households or 92 per cent of the population (2015). Far behind in terms of population coverage (43 per cent) but very close in terms of number of households (almost 27 million) is Brazil’s Cadastro Único, followed by Indonesia’s Unified Database (25 million households, 40 per cent of population).

Interestingly, this is far lower than the number of beneficiaries registered for China’s Dibao program registry of beneficiaries, which comprehends 78 million households (Honorati, Gentilini and Yemtsov 2015) – representing, however, only 6 per cent of China’s population.

Source: Honorati, Gentilini and Yemtsov (2015) and authors’ updates (online survey and recent literature). Note: Mauritius and Lesotho have registered 0.04 million beneficiaries.

**4.9 TAKE-AWAY LESSONS**

- Integration of information and data within the SP sector could potentially yield several policy and operational dividends. The extent to which these are achieved in practice will depend on the ultimate set-up of the selected Integrated System for Information Management. This choice will also affect the extent of potential risks and tradeoffs – which need to be carefully evaluated and counteracted.

- Potentially, the greater the interconnectivity, the greater are the gains in efficiency and effectiveness of service delivery. The key issue is therefore the level of coordination and interoperability achieved, not the creation of a super-sized system or database that serves all purposes. It does not matter whether the system is set-up as a ‘Social Registry’, ‘Integrated Beneficiary Registry’ or ‘Virtual Social Registry’ – what matters is that the approach chosen responds to a country’s needs, is appropriate to its context and is affordable and sustainable.

- A system that guarantees full integration within the Social Protection sector and beyond, in accordance with the right to privacy, would establish a direct (e.g. web service) link to all Social Assistance Programme MISs, Social Insurance MISs, and any other relevant Government MISs.

- Integration is mainly a policy issue requiring political and institutional arrangements rather than technical ‘fixes’ and different countries pursue different policy objectives with integration (affecting their design choices): they may be choosing to facilitate the combined oversight of programmes, the consolidation of targeting, and/or the integration of operations and services.

- Certain set-ups for integration will only be achievable in certain contexts: a country’s historical trajectory and ultimate ‘endowment’ has a great weight in determining choices (e.g. existing infrastructure, capacity, etc.)
5.2 NEEDS ASSESSMENT AND AGREEMENT ON BROAD DESIGN PARAMETERS

Design choices need to be defined through evidence, carefully analysing gaps in service provision and separating desire from need. In order to achieve this, broad consensus needs to be built among all key stakeholders. This can be on the basis of a comprehensive needs assessment and on-going participatory planning, with the objective of agreeing on broad design parameters. Using the creation of an Integrated System for Information Management as an example (this can be broadly applicable to programme MIS too), this will include:

- Taking stock of the broader Social Protection and E-Government context, to define objectives and understand opportunities and constraints
- Taking stock of existing programmes and their potential for integration, including the quality of existing programme business processes and whether/how to redesign/integrate these;
- Understanding specific information requirements for different levels of users (primary, secondary and tertiary), including policy makers from other sectors

<table>

| Broad Social Protection context (policy & legislation) | • What is the National SP policy? Priorities? Does this reflect plans for integration? How? What are the policy priorities in terms of integration (see Section 4.5)?
• (Stakeholder mapping) Who is in charge of delivering social assistance and social security in country, at both central and decentralised level (primary users)? What other stakeholders are involved (secondary users)? Which further actors may have a stake (tertiary users)? What are these actors’ interests? What are their (information and management) needs that integration can help address? What resistance could be encountered?
• What are the legislative foundations for Social Protection and for integration?
• What are the gaps?
  • What is the current degree of fragmentation or integration within Social Assistance and between Social Assistance and Social Insurance? What are the existing mechanisms for horizontal and vertical coordination?
  • What is the level of decentralization? What capacity is there at local level? |

5.1 OBJECTIVES

Having completed this section, the participant will have an understanding of:

- The main steps involved in setting up an MIS or Integrated System for Information Management
- The importance of a Needs Assessment and a Feasibility Study and what questions these should be asking
- Several considerations, including potential risks, during design and implementation

Setting up a programme MIS is a challenging undertaking, which is compounded by a lack of standards and guidelines. Consequently, many countries, especially in sub-Saharan Africa, have been experimenting with a number of pilot programmes that implement programme MIS. Unfortunately, some of these experiments have been costly. For example, some countries have procured MIS software without accompanying source codes, while others have been forced to pay expensive licenses in instances where source codes were not supplied alongside other MIS deliverables. In other cases, vendors have oversold expensive customized MIS solutions where standard off the shelf products would have been sufficient for the needs of the particular programme. Very often, the underlying problem has been lack of sufficient capacity of the commissioning body.

These risk are even larger for Integrated Systems for Information Management – which require significant levels of policy coordination to fulfil their objectives at full. Of course these challenges are not insurmountable. In fact, with better understanding of the key factors and risks, improved systems can be set up to best address the needs of SP schemes and systems.

Broadly speaking, we focus on three key steps: (i) conducting a needs assessment and agreeing on broad design parameters; (ii) conducting a feasibility study; and (iii) developing and implementing the selected solution.
KEY STEPS WHEN SETTING UP A PROGRAMME MIS OR AN INTEGRATED SYSTEM FOR INFORMATION MANAGEMENT

<table>
<thead>

</tr>
<tr>
<td>• What are the specific information needs of all key actors (primary, secondary and tertiary - national and local, government and civil society, implementation and policy, etc.)? Why are these needs important? How will this information be used? What is the order in terms of priority?</td>
<td></td>
</tr>
<tr>
<td>• What data will be needed to feed into the core business processes supported?</td>
<td></td>
</tr>
<tr>
<td>• Has the amount of data collected been limited by keeping data focused on core objectives and processes?</td>
<td></td>
</tr>
</tbody>
</table>

A feasibility study aims to objectively and rationally uncover the strengths and weaknesses of the proposed design based on a wide range of parameters, that ultimately define the prospects for success. A good feasibility report should set out a clear road map on the design and implementation of the Programme MIS or integrated solution for data and information management at a strategic level.

In many developing countries, policy makers assume that programme MISs and integrated systems for information management are a ‘technical tool’ that is best delivered by ICT consultants or experts. However, these should be thought of holistically as broad systems that enable the flow of information within and beyond Social Protection programmes and are, therefore, policy tools that should find space in national SP policy agendas. Fortunately, this is increasingly happening in several developing countries - e.g. Kenya (see Case Study and Box 10).

Box 10: Kenya’s Single Registry

Kenya’s National Social Protection Policy (NSPP) clearly defines the nature and scope of the Single Registry and SP MIS. According to NSPP, the Single Registry is designed to: (i) provide increased harmonization and consolidation of fragmented schemes; and (ii) enhance the responsiveness of social protection initiatives to increase its capacity to quickly scale-up in response to rapid-onset crises. The NSPP also vests the responsibility for collection and management of data in the respective stakeholders implementing various social protection programmes. See Case Study in Section 6.2 below.

Source: Barca, 2017

However, not all developing countries have put in place social protection policies with clear agendas on MIS or integration. To avoid potential pitfalls, developing countries should therefore invest in feasibility studies. Such a study would address the following issues (see Table 6 below):

Table 6: Key feasibility parameters and questions

<tr>
<td>• Is the existing governance structure strong enough to ensure vertical and horizontal coordination and lead development and management phases? If not, how could this be strengthened?</td>
<td></td>
</tr>
<tr>
<td>Implementation capacity</td>
<td></td>
</tr>
<tr>
<td>• What capacity is there at all levels of Social Protection governance to implement such a project? What are the gaps that need addressing (number and qualifications of staff)?</td>
<td></td>
</tr>
<tr>
<td>• Is there in-house IT capacity that can be leveraged? If so, how will this be used? If not, how will external providers be managed?</td>
<td></td>
</tr>
<tr>
<td>• Is there a network of staff at local level (e.g. social assistants) that can be called upon? How can these most effectively be used?</td>
<td></td>
</tr>
<tr>
<td>• What is their capacity in terms of data collection (either through a census survey or on-demand)?</td>
<td></td>
</tr>
<tr>
<td>• Overall, what are the proposed roles and responsibilities of various actors involved in setting up, managing and using the system?</td>
<td></td>
</tr>
<tr>
<td>Infrastructure requirements</td>
<td></td>
</tr>
<tr>
<td>• What are the hardware requirements of the proposed model? Do these respond to country constraints (durability, etc.)? Are these already available at all levels of governance or will they need to be procured? If so, how? Expected costs?</td>
<td></td>
</tr>
<tr>
<td>• What are the telecommunication systems/network requirements? Do these respond to country constraints (availability of internet, power, etc.)? What back-up options exist?</td>
<td></td>
</tr>
</tbody>
</table>

35primarily drawn from Lindert et al (2016)
36Specifically, elements of this table are adapted from the World Bank’s draft ‘Assessment Tool for Social Registry Information Systems’.
Outsourcing is essential where capacity is not available in-house, but requires careful contracting and management. For example, during the development of the software, it is necessary to support the supplier by internally establishing two teams:

1. Steering: to ensure that the MIS is delivered within scope and on time.
2. Technical: responsible for monitoring the tasks and deliverables of the project.

Further best practice (to be incorporated in ToRs if managed externally) is to:

- Adopt iterative prototyping, whereby the system is designed and used to iteratively customise and incorporate feedback from users (one module at a time).
- Use open-source software, acknowledging the high costs of making changes to proprietary software. For any other proprietary third party software used, the suppliers should be asked to provide perpetual and valid license for at least a period of five years and ensure software is procured with accompanying source codes.
- Ensuring the MIS software includes all standard data checks such as format masks, drop-down menus, data value parameters, warnings of repeating names, and cross-reference checks.
- Ensuring ‘segregation of functions’: pre-defining roles and privileges of each user of the MIS system so as to prevent violations of security and any misuse of the MIS application.
- Build in-house capacity to develop and update the MIS, for example by ensuring that contracts have clear provisions to allow suppliers to hand-over all the source code and technical documentation of the system without any preconditions.

### 5.3 DEVELOP AND IMPLEMENT SELECTED SOLUTION

As discussed extensively above, the ‘road-map’ set out by the Feasibility Study should primarily focus on how the overarching strategy for implementing the selected solution (e.g. programme MIS or specific approach to developing an Integrated System for Information Management) will be effectively pursued. How this can be achieved in practice is beyond the scope of this Module, but is discussed in Module COO and Module GOV.

In this section we focus on the ‘IT components’: the development (and implementation) of the MIS or Integrated MIS software, the database/registry creation, the hardware procurement and the choice of telecommunications system.

#### 5.3.1 Software development

There are two main options for this: develop the MIS software in-house (if there is sufficient capacity) or tendering it out to an external provider. For example:

- Mozambique opted to develop and locate its MIS at the Ministry of Finance because it had sufficient resources to develop, host, and maintain it.
- Kenya outsourced the development of its ‘Single Registry’ (Integrated Beneficiary Registry) and the modernization of its cash transfer MIS to an external software firm that had local presence (important because it enables the supplier to provide ‘handholding’ throughout implementation and fix any potential software glitches within a minimum guarantee period, e.g. a year).

#### 5.3.2 Database/registry creation

An MIS can only function if it is fed by a database/registry that contains accurate, up-to-date data (garbage in—garbage out). This requires:

- a. Ensuring a strong approach to data collection and validation (see Modules X, Y and Z).
- b. Ensuring contents and formats such as names and identification numbers conform to those contained in the MIS’ data dictionary. The length of fields and content structure should be standardized for aggregation and reporting.

#### 5.3.3 Hardware procurement

As discussed in Section 3.3, MIs need to be supported by adequate hardware. Best practice in ensuring this is the case includes:

- Choosing hardware resources on the basis of the application software requirements of the MIS.
- Carefully defining hardware specifications to ensure adequate memory, disc space and processing capacity; sufficient resilience to extreme conditions (high or low temperatures, rain, dust, etc.).
- Ensuring availability and appropriateness for local levels of administration, considering cost-effective technology (e.g. use of tablets, smartphones, etc.).

---

### KEY STEPS WHEN SETTING UP A PROGRAMME MIS OR AN INTEGRATED SYSTEM FOR INFORMATION MANAGEMENT

- **Financial costs & sustainability**
  - What are the estimated start-up costs of the proposed model (including hardware and training costs)?
  - What are the estimated costs of operating the proposed model (including staff requirements)?
  - Is an adequate source of funding guaranteed and sustainable over time?

- **Intended users**
  - How will the system ultimately be used?
  - How can use be most effectively enhanced?

- **Potential positive impacts**
  - What are the expected positive impacts of the proposed system?
  - How could these best be achieved? See list in Section 4.4 as an example.

- **Potential negative impacts**
  - What are the negative impacts and how can these be mitigated?
  - E.g. privacy and security risks, excessive costs, unsustainability, etc.

- **Conclusions and Recommendations**
  - What are conclusions?
  - What are key recommendations?

---

### Source:

Authors

The feasibility study would provide essential guidance as to how to implement the proposed project effectively – or could provide the basis for deciding the overarching project is unfeasible.

5.3 DEVELOP AND IMPLEMENT SELECTED SOLUTION

As discussed extensively above, the ‘road-map’ set out by the Feasibility Study should primarily focus on how the overarching strategy for implementing the selected solution (e.g. programme MIS or specific approach to developing an Integrated System for Information Management) will be effectively pursued. How this can be achieved in practice is beyond the scope of this Module, but is discussed in Module COO and Module GOV.

In this section we focus on the ‘IT components’: the development (and implementation) of the MIS or Integrated MIS software, the database/registry creation, the hardware procurement and the choice of telecommunications system.

5.3.1 Software development

There are two main options for this: develop the MIS software in-house (if there is sufficient capacity) or tendering it out to an external provider. For example:

- Mozambique opted to develop and locate its MIS at the Ministry of Finance because it had sufficient resources to develop, host, and maintain it;
- Kenya outsourced the development of its ‘Single Registry’ (Integrated Beneficiary Registry) and the modernization of its cash transfer MIS to an external software firm that had local presence (important because it enables the supplier to provide ‘handholding’ throughout implementation and fix any potential software glitches within a minimum guarantee period, e.g. a year).
5.3.4 Telecommunications system (data-sharing) set-up

Data collected through an MIS, whether programme specific or integrated, is useless if it is not accessible by a wide variety of actors – and ultimately used. Best practice in setting such systems up include:

- Ensuring data is accessible and functional at sub-national level using the most cost-effective and appropriate telecommunication technologies available in-country, where possible sharing data through web-service access (not batch processes, using CDs or email).
- Investing in network infrastructure readiness
- Where possible, automating data sharing through pre-defined formats/templates/applications
- Ensuring adequate measures for data security and privacy (see also Section 4.7.2)
- Clearly documenting protocols for quality controls on information before it is submitted over the Internet or transferred by batch process

5.4 TAKE-AWAY LESSONS

- Setting up a programme MIS is a challenging undertaking, and risks are even larger for Integrated Systems for Information Management. A better understanding of key factors and risks can help to set up improved systems to best address the needs of SP schemes and systems.

- Three key steps: (i) conducting a Needs Assessment and agreeing on broad design parameters; (ii) conducting a Feasibility Study, and (iii) developing and implementing the selected solution.

1. The Needs Assessment, accompanied by on-going participatory panning, should aim to define broad design parameters by: taking stock of the broader Social Protection and E-Government context, taking stock of existing programmes and their potential for integration, and understanding specific information requirements for different levels of users.

2. The Feasibility Study should aim to objectively uncover the strengths and weaknesses of the proposed design, in order to improve its chances of success. It should focus on the following areas: institutional capacity, implementation capacity, infrastructure requirements, responsiveness to intended users’ needs, potential positive and negative impacts and subsequent recommendations.

3. Developing and implementing the selected solution is primarily an issue of capacity, governance and coordination. However, best practice does emerge for the purely ‘IT components’ (software development, database/registry creation, hardware procurement and telecommunications system set-up).

### CASE STUDIES

The following chapter sets out three country case studies: (i) Zimbabwe, exemplifying a case of programme MIS that was designed to act as a Social Registry. Interestingly, the Zimbabwe cash transfer design bears close resemblance to neighbouring Zambia’s and Malawi’s social cash transfer schemes. (ii) Kenya, highlighting the use of an Integrated Beneficiary Registry set up to consolidate information on five national social assistance programmes; and (iii) South Africa, illustrating the role of an integrated MIS serving a number of national schemes.

#### 6.1 ZIMBABWE’S HARMONISED SOCIAL CASH TRANSFER SCHEME AND ITS MIS

Zimbabwe is currently in the process of putting in place a national social protection policy. However, that has not stopped the Ministry of Labour and Social Services (MoLSS), Department of Social Services (DSS), from designing a flagship social cash transfer programme for labour-constrained and extremely poor households. The social cash transfer programme was established as part of the revised National Action Plan for Orphans and Vulnerable Children (NAP II) 2011-2015 as well as of broader DSS social protection programming.

The Child Protection Fund (CPF) has three main pillars. The first is to reduce poverty experienced by approximately 55,000 extremely poor households, including those with orphans and other vulnerable children, by implementing a national cash transfer programme and thereby positively benefiting children and women’s health and well-being. The second is to enhance all vulnerable children’s access to effective child protection services, including protective services (legal, welfare, judicial) to child survivors of violence, exploitation and abuse. The third is to facilitate improved access to basic education for poor orphans and other vulnerable children in Year 1.

To support the harmonized cash transfer (HSCT) programme, CPF contracted the design of the programme’s manual of operations and its MIS to an external consultancy firm. The programme MIS was designed and developed on the back of a comprehensive review of the capacity, potential and use of the social cash transfer scheme databases. Thus, the MIS systematically and comprehensively captures the information requirements documented in the manual of operations of the harmonized cash transfer programme. The HSCT conducted mass registration (outsourced to Zimbabwe’s Bureau of Statistics [ZIMSTATs]) in the target districts in order to create a comprehensive NAP II database. To date, the NAP II database contains information on 539,057 households across 24 districts.
As set out in Figure 5, the SP programmes that are harmonized or designed to link to the NAP II registry include:

- Harmonised Cash Transfer Programme (HSCT): On the basis of the NAP II registry, the programme’s MIS applies two sets of selection criteria: (i) extreme poverty, meaning the household members are living below the food poverty line and are unable to meet their most urgent basic needs; and (ii) if the household has no labour capacity, i.e. it has no able-bodied household member in the age group 18 to 59 who is fit for productive work. Based on the dual criteria, HSCT currently benefits 55,507 households in 20 districts.

- Basic Education Assistance Module (BEAM): The Basic Education Assistance Module (BEAM) was conceived as part of the Enhanced Social Protection Project (ESPP), which was launched by the Government of Zimbabwe in the year 2000. Even though the beneficiaries of BEAM are not derived from the NAP II registry, the intention has always been for the beneficiaries of HSCT to receive BEAM as a complementary (cash plus service) benefit.

- AMTOS: the beneficiaries of the HSCT are intended to receive AMTOS, a health insurance for poor households as a complementary benefit.

Figure 8: NAP II Registry as envisioned by the child-sensitive social protection framework

Figure 9: Programmes that form Kenya’s Single Registry

Authors. Note: Boxes indicate databases, circles indicate MISs, bold lines indicate direct link (e.g. web service access), dotted lines indicate indirect link (batch process, CDs etc.), double arrows indicate info flowing in both directions, single arrows indicate info flowing in just one direction.
6.2.1 Background and historical evolution

Historically, social protection programmes in Kenya were not well coordinated and fragmented, presenting duplications and inconsistencies, and led by different agencies – resulting in a lack of efficiency (World Bank, 2012). Over time, there was growing recognition that there should be a systematic approach to data and information management across the sector.

Kenya’s Social Protection Policy, which was gazetted in 2012, comprehensively addressed policy coordination, including the institutional framework and management information systems needed to make it happen. The policy also envisioned the country’s Single Registry as playing a central role in establishing a coherent and scalable approach to social protection, “The Government recognizes the need to establish a management information system (MIS) for social protection in Kenya”[39]. This vision was also reflected in the Medium term plan (MTP) of Kenya’s Vision 2030 and was strongly led by the National Social Protection Secretariat.

In 2011, the process to achieve such integration was not clear. Some of the programmes that were going to be integrated did not have an electronic database or related MIS, while none of the existing databases could speak to each other and no standardisation of data existed across databases (for example there were no use of standard geographic locations across programmes). To tackle these problems, in 2011 a Working Group was established with members from the country’s five core programmes to start discussing standardisation. Recommendations developed on the basis of on-going assessments led to a first achievement, with government-led cash transfer MISs harmonised in 2013. With technical assistance from WFP, full integration across programmes was achieved in 2014-2015, including integration with the country’s Civil Registration authority. The system went into full use by April 2015 when linkage to Civil Registration was established.

6.2.2 Institutional arrangements

The National Social Protection Policy vests the National Council for Social Protection[40] with the overall strategic direction for social protection. Support and coordination is provided by the Social Protection Secretariat, located within the Ministry of Labour and East African Affairs (MLEAA). Since Kenya’s Single Registry is essentially a warehouse, holding information on all the beneficiaries of the national social protection system, data collection and updating is undertaken by individual programme MISs.

The Head of the Social Protection Secretariat is fully responsible for the overall management of the Single Registry. Technical administration (data backup and ensuring that the system is up and running) is undertaken by an MIS Coordinator supported by two assistants. Since effective functionality of individual programme MISs is important to ensure update of the Single Registry, an MIS working group was created to bring together MIS specialists from individual programmes – coordinated by the MIS Coordinator at the Secretariat. This group leads in providing technical oversight to Single Registry development. An external consultancy firm, Development Pathways was contracted initially by DFID and more recently by World Food Programme to build and maintain the Single Registry.

6.2.3 How Kenya’s single registry is structured in practice

6.2.3.1 Data sources and linkages

As discussed above, the main source of data for the Single Registry are the country’s five social protection programedatabases. The broad data set of information on Single Registry and programme database is set out in Table 7 overleaf.

Table 7: Information kept within the Single Registry

</table>

To ensure that data on the Single Registry and programme MISs is verified (i.e. accurate), the Single Registry is also linked to IPRS – a department in the Ministry of Interior and Coordination that maintains 30 million plus National Population Register – and links to other government and private sector providers using an automated softwaremechanism (web service). It is worth emphasizing that the registration of potential beneficiaries for safety net programmes in Kenya was historically conducted by recording personal information from formal forms of identification, including national identity cards and passports. The integration of Single Registry and IPRS enables NSNP to verify details of their beneficiaries and authenticity of potential beneficiaries before enrolling them.

6.2.3.2 How data is collected and updated

Data collection and updating for Kenya’s Single Registry is undertaken by individual programmes. Owing to the fact that these programmes have been set up for different purposes, their registration (data collection) approaches and data needs are different. There are plans currently to standardise information collection.

In terms of registration, except for HSNP (which followed a ‘pure’ census approach for its second phase registration), other social assistance programmes in Kenya undertake a ‘push’ registration on an annual basis. For the purposes of this case study, Push Registration is defined as a process where government purposely and periodically goes to communities to register a set number of beneficiaries through ad hoc committees and with help of local administrators, without resorting to a door to door census (Kidii and Hossain, 2014). Table 3 describes the historical data collection process by each individual programme that forms the Single Registry.
### Table 8: Approaches to data collection and updating

<td>Push Registration (variant on census survey approach)</td>
<td>Registration is undertaken with support of contracted cooperating partners based on programme targets.</td>
</tr>
</tbody>
</table>

Except for HSNP and WFP's CTM which are purely electronic, all the other NSNP programmes (CT-OVC, OPCT, PwSDCT and UFSP-CT) register households manually (first data-capture). The paperwork is then transported from the field to the National Office for transcription into the programme MIS. Recently the DSD decentralized the transcription process from the National to the County level. So far, there has been an indication of a general improvement in the quality of data captured and timeliness of the registration process, attributed to nearness to the data source.

Each programme has specific operational guidelines to ensure currency of their data based on their targeting approaches. For example, three programmes (OPCT, PwSDCT and CT-OVC) are categorical schemes that are poverty targeted. These programmes continuously update their data to exit beneficiaries who are no longer eligible. For instance, a senior citizen who has died or an orphan who has turned 23 are exited from OPCT and CT-OVC respectively. When this happens, the Single Registry is automatically updated. Single Registry is also updated to bring in new replacements for beneficiaries that have been exited. This is very common with OPCT. Finally, as discussed above, large enrolments of new beneficiaries are normally undertaken annually based on government’s budget allocations and in line with expansion plans.

### 6.2.3.3 How data is transferred

Until early 2015, the transfer of data from programme MIS to the Single Registry was not automatic. This meant that data had to be moved manually and the process did not guarantee up-to-date data at the Single Registry. As a result, two methodologies for automatic transfer of data between individual MISs and the Single Registry were tested: (i) Data exchange using web services, and (ii) Automatic replication using Microsoft SQL tools. A technical assessment of the two showed that the latter was appropriate for the Kenyan context because: (i) all the programme databases were set up with Microsoft SQL Server; (ii) technically, it was possible to configure a homogenous replication mechanism; (iii) using web service option would have required more programming time. Therefore, an automatic replication of data from the CT-OVC, joint OPCT/PwSD-CT and the HSNP MISs to the Single Registry was configured using an SQL server, giving each programme database a mirror copy on the Single Registry server (and thus acting as a real-time backup).

Apart from sending data to Single Registry, each programme MIS can connect to the Single Registry and access its data using web service (“Bio Data Verification”). The web service link enables programmes (through their MISs) to access data on beneficiaries for the purposes of verification of potential beneficiaries before they are enrolled. “Bio Data Verification” web service specifically ensures that adult members (with national IDs) of potential beneficiary households are: (i) authenticated against the IPRS Population Register; (ii) checked against Single Registry to determine whether one member benefits from one or multiple programmes.

The Single Registry currently works as a tool to support programme monitoring and coordination of social protection sector. As such, its primary users are programme staff at the national and sub-national level. Therefore, programme staff working at national as well as decentralised units of government (counties and sub-counties) are also provided access to Single Registry. In fact, the Single Registry ‘enquiries module’ has become an effective tool to respond to programme queries, as it is accessible over the Internet. The enquiries module is used to check whether beneficiaries have been enrolled by programmes or whether payments have been delivered to beneficiaries. Going forward, there are plans to deepen the use of Single Registry data by targeting other government entities - e.g. other ministries and counties (communication) – at both national and local level as well as providing an access portal to beneficiaries using national ID as search parameter.

Data from the Single Registry to external stakeholders is transferred in excel format by email or on disk. The Social Protection Secretariat has developed and signed off data sharing protocols that define: (i) Procedures for application for use of Single Registry data; (ii) Procedures for assessing the application; (iii) Procedures for approval, sharing and; (iv) disposal of data. Examples of institutions that have requested data based on the protocols include: other Social Protection Programmes; other national government institutions e.g. Parliament; implementation partners e.g. Payment Service Providers; Donor organizations i.e. DFID, DFAT, World Bank, UNICEF, WFP; international NGOs; and National NGOs.

### 6.2.3.4 How data is processed and used for targeting

After data is captured on Programme MISs, each undergoes a validation based on the procedures defined in Programme Operations Manuals. Each core step (registration, determination of eligibility and enrolment) is supported by individual programme MISs: the data that is consolidated in the Single Registry is only from programme beneficiaries.

Importantly, however, the overarching integration has added value to the verification phase for each programme in two ways: (i) by enabling a check of potential beneficiaries against the Single Registry to determine households that could be benefitting from more than one programme (ii) by comparison with IPRS’s national population register to determine accuracy of the information collected on potential beneficiaries (especially ID numbers, names, date of birth and sex). The potential beneficiaries who do not meet the criteria (i.e. already enrolled in another programme) are de-registered.

### 6.2.3.5 How information is used

The Single Registry through its MIS platform is used for organising and managing the data for social protection programmes in Kenya. The Single Registry enables the flow and management of information within and between social protection programmes and in some instances, other sectors.
The information is utilised by local and national government, policymakers, social safety net programs designers and managers. Kenya’s Single Registry responds to the following stakeholder issues:

- **Prevention Error/Fraud.** Information in the Registry is run against data on 30 million IRS’ National Population Register, allowing programme managers to be sure that beneficiaries’ details are accurate/verified.

- **Programme Efficiency and Effectiveness.** Crosscheck is made whether beneficiaries enrolled in a programme are on the payroll, and whether the number of beneficiaries scheduled to be paid equals those actually paid.

- **Monitoring Programme Implementation.** Single Registry supports programme monitoring, and has a specific report that allows monitoring of the selected indicators across programmes.

- **Planning Expansion of Social Protection Programmes.** The expansion plan of the National Safety Net Program has been integrated with the Single Registry so that users can cross-reference attainment against objective for any programme.

- **Foundation for Establishment of Common Delivery Systems.** With a consolidated payroll of beneficiaries from existing cash transfer schemes; the Single Registry is a key resource for creating other common delivery systems, including payment systems, which will reduce the costs associated with delivering benefits.

- **Basis for Emergency Response.** HSNP sub-registry contains bank account details for households in four poorest counties (Turkana, Wajir, Mandera and Marsabit) enabling emergency response in case of drought.

Since February 2016, SP Secretariat also provides open web access to the data on key performance indicators of the NSNP.

**Figure 10: Sample of Single Registry summary statistics**

The Social Protection Secretariat has developed comprehensive data protection and sharing protocols. The purpose of the NSNP data sharing protocols are fivefold: (i) Provide a framework for the secure and confidential sharing of information (ii) Ensure personal information is handled in a sensitive manner and only disclosed on need-to-know and need-to-use basis (iii) Provide a basis where anonymised data about an individual beneficiary or member can be shared without consent in a form where the identity cannot be recognised (iv) Create a transparent procedure to increase usage of the National Safety Net Program (NSNP) data to layer additional services to cash transfer beneficiaries; and (v) Ensure that the rights of programme beneficiaries especially their privacy is not infringed as enshrined on the Kenyan Constitution and other International conventions. The data sharing protocols are based on the Kenyan Constitution, Kenya’s Data Protection Act - 2013 and other international conventions such as Council of Europe’s Convention, United Nations Guidelines Concerning Computerized Personal Data-Files, OECD Guidelines on the Protection of Privacy and Trans-Border Flows of Personal Data and Universal Declaration of Human Rights.

Summary and aggregated data on the programmes that form Single Registry can be accessed through a public portal. However, Personal Data or request for data on beneficiary household listings is accessed on need to know and need to use basis. For all data requests, the applicants must attest to data confidentiality agreements that have specific guidelines on use and disposal of the data.

**6.2.4 Main challenges and lessons learned**

The management of information for the different social protection programmes in Kenya has been significantly improved since the inception of the Single Registry. Social Protection programmes in Kenya are better managed and operated, while the coordination, oversight and monitoring of the social assistance sector is made possible by Single Registry. The Single Registry has enabled the government and other key stakeholders to conceptualise the coordinated of the programs in a clear and coordinated manner.

Key lessons from the implementation of Kenya’s Single Registry include the following:

- Approaches to developing Integrated Systems for Information Management should be construed more broadly as a policy tool. Kenya’s Social Protection policy underscored the need for the Single Registry and envisioned the set-up of individual programmes with functional MISs populating the Single Registry.

- Adequate investment should be made to deliver quality Registry design, based on needs assessments and feasibility studies (see also Section 1) – both important for long term sustainability.

- The development of a Single Registry should be phased. Phasing helps ensure:
  - Ease of managing project sub-components
  - Incorporating lessons from previous phases in next phases
  - Less risk of failure and risk of overwhelming existing capacity
  - Ad-hoc strengthening of business processes and systems

The key challenges that have been experienced during the set up include:

- **Conceptualisation:** at first, it was difficult to technically conceptualise how social assistance programmes could be coordinated. Now the model is clear and logical, but it took a lot of assessment and thinking to get there.

- **Coordination:** the Secretariat had to undertake a massive task to actually coordinate individual programmes to invest time and resources in an MIS. Now each social assistance programme owns its own MIS and is a core part of the Single Registry. It works for all the actors involved.

- **Resources:** in order to save time and money in the future, an upfront investment is needed. Over the years, various development partners have stepped in to support the Government in making this happen.
The next stage in the development of the Single Registry will be to ensure that all programme MISs can be managed at district level – through a web-based system – and that information on beneficiaries can be updated as close to real time as possible. The broader plan is to also bring on board other components of the social protection system such as the National Social Health Insurance scheme and the National Social Security Fund (NSSF).

6.3 SOUTH AFRICA’S SOCPEN

The Republic of South Africa’s Department of Social Development (DSD), established in 1929, runs a comprehensive system of social assistance grants and processes 16,991,634 grants monthly (collected by just over 11 million recipients). The cost is estimated to be 3.5 per cent of the country’s gross domestic product. The grants are processed using a legacy information management system called SOCPEN, which started in the 1930s. South Africa's social protection system is similar in two ways to the social security system in high-income countries—its programs are means tested and national in coverage. Responsibility rests with the DSD and South Africa Social Security Agency (SASSA). While DSD is responsible for policy, legislation and oversight, SASSA is in charge of program implementation.

6.3.1 Objective and institutional arrangements of SOCPEN

SASSA is mandated by the South African Social Security Agency Act to: ‘… ensure the provision of comprehensive social security services against vulnerability and poverty within the constitutional legislative framework.’

SASSA has MoUs with other ministries and government structures and has succeeded in setting up online interfaces for data exchange with the Department of Home Affairs and PERSAL, the government payroll system.

6.3.2 How SOCPEN is structured in practice

SOCPEN runs on mainframes located at SITA. Its enterprise database, Adabas, manages more than 2300 concurrent users and has a register of more than 16 million beneficiaries.

The system operates throughout SASSA offices but cannot be accessed through the Internet for online application processing. Applicants must complete application forms in the presence of a SASSA officer and these are entered into SOCPEN, which allows real-time tracking of progress and reduces problems of lost or misplaced forms.

6.3.2.1 Data sources

SOCPEN is a primary database for beneficiary information management. As shown in Figure 7, it is linked to other data sources, including:

- Applicants of the six social grants feeding into SOCPEN
- A file tracking system providing real-time information on the status of social grant applications
- Livelink, a document management system that scans and manages records of grant recipients.

SOCPEN interfaces with other government MISs, the most important of which is the Department of Home Affairs and can provide real-time information from the population register. For example, when a death is reported, the information is conveyed to SOCPEN immediately leading to termination of payments. Data is also used to establish beneficiary status (for example, age cut-offs).

6.3.2.2 Data collection

Given that SOCPEN is a demand-based system, by which potential beneficiaries apply to the program at local SASSA office registration points, the process of data collection and registration is on-going, allowing for regular updating and re-certifying. Box 11 has more details on the social grants lifecycle.

**Source:** Developed by authors on the basis of Chirchir (2011).

An online interface has been established with PERSAL, to crosscheck income data. Other adhoc data sources (not linked online) for this include: the Unemployment Insurance Fund; Government Employees Pension Fund; payroll system of the Defence Force; National Treasury (to verify beneficiary banking details); Department of Basic Education’s learner database; and special investigations unit (to identify fraudulent grants).

Innovatively, biometric systems are in place for beneficiaries to collect their money and prove their identity, including fingerprints and voice recognition.

**CASE STUDIES**

*Figure 11: Overall structure of SOCPEN*

**Source:** SOCPEN fact sheet, 31 March 2016 and useful integrations from Caesar Vundule and Carin Koster. The current estimate of South Africa’s population is 54 million.
The social grants lifecycle in South Africa starts with applications made on demand at local SASSA office registration points. Details captured include personal information, address, income, deductions, age and disability. Applications are screened with applicants identified and proof of income provided. If there is Internet access, grants officers enter details into SOCPEN. Legally, applications should be processed within 21 days. However, current initiatives aim to reduce turnaround time to 24 hours.

The next step is approval or rejection based on applicant information provided, and criteria defined for the means test. Applicants are informed of outcomes through notification letters.

Once notified, applicants are enrolled into the scheme. Then SOCPEN’s payroll produces a payment schedule aggregated by provinces and payment service providers. SASSA uses three payment methods: bank deposits; hand delivery; and pickup from a post office.

SOCPEN monitors eligibility of approved beneficiaries. Routine maintenance certifies if beneficiaries are alive and updates the poverty status of existing beneficiaries. SOCPEN system ring-fences beneficiaries due for review and notifications are prepared. Those still eligible are reinstated, while those who skip reviews are suspended.

Source: Barca and Chirchir (2014)

6.3.2.3 How information from SOCPEN is used

SOCPEN handles 2300 concurrent users. This is impressive for a legacy system that has consistently processed more than 16 million grants a month. Since social security implementation is handled by one agency, it can be argued that South Africa operates a ‘single window’ for processing applicants.

SOCPEN also:

- processes applications for the country’s six social grants
- determines beneficiaries from the list of applicants
- maintains the payroll for the monthly 16 million plus grants
- automatically produces a list of beneficiaries to be re-assessed.

The system has limits, however. SASSA employees are the main users of the information kept by SOCPEN. Moreover, SOCPEN is not an organisation-wide system and so not all of SASSA’s operations are computerised. Indeed, SASSA also has to maintain other operational MISs for example, financial, human resource management, call centres and a geographic information tracking system.

Plans are underway to migrate SOCPEN to a graphical user interface while maintaining its robust database platform (Peterson and Appel, 2012). The new system will integrate current services with compliance services, back-office functions and business intelligence services.

6.3.3 Further pushes for integration: the national integrated social Information system

SASSA’s plans to migrate to a graphical user interface have run in parallel with plans to integrate the social information needed by higher levels of government. This need originally came from the national War on Poverty Campaign launched in 2007 by the Office of the President after a 10-year review of anti-poverty services offered since Independence. The rationale for creating a new NISIS was to develop cross-ministry, anti-poverty strategies and gather information on the conditions of the poor. SASSA’s on-demand system was insufficient for this since it does not have a complete profile of the poor. A feasibility study and proof-of-concept for NISIS were completed in 2009, financed directly by the Treasury.

Since then, as with most large conceptual ideas, NISIS’s development has been a journey. In 2009, a formal partnership was established between the War on Poverty Campaign and the Department of Rural Development and Land Reform. The department took ownership of the project and has enabled the on-going development of NISIS in support of its Comprehensive Rural Development Programme, which focused on household profiling and service referrals capabilities. The DSD was to lead overall coordination but it never did so, partly because NISIS had no institutional and legal framework and no structure. SASSA has been almost cut out, such that SOCPEN data has never been fed into the NISIS database. Similarly, the Treasury has not supported the project due to ‘general scepticism over large scale IT projects’ (Da Silva, 2012).

As a consequence, some provincial governments are experimenting with playing a stronger role in coordinating the social policy within their remit, including North Cape and Mpumalanga provinces and in Johannesburg.

Despite any success at provincial level, the NISIS remains far from being what it set out to be. The DSD is trying to reconceptualise the NISIS to align it with departmental priorities and focuses on internal coordination and implementation of an integrated service delivery model.

6.3.4 Main challenges and lessons learned

6.3.4.1 SOCPEN

SOCPEN is stable, supports most grant operations and interfaces with some other government MISs to crosscheck information and prevent fraud. However, it has its limits, including:

- reaching its ability to be customised and being overtaken by many technological changes
- processes producing substantial volume of paper and forms
- not being an organisation-wide system covering all SASSA operations
- positioning SASSA, so it has to maintain other operational MISs, which is inefficient and leads to duplication of data storing (making reporting, monitoring and evaluation difficult)
- linking with other MISs but not always in real time
- not being set up to integrate data and information management, which means its overall focus is on managing operational processes for grant delivery rather than on policy coordination and oversight.

Despite these limitations, several lessons can be drawn from South Africa’s experience:

- **Old is gold.** Even though it is a legacy system built on a non-graphical user interface based on mainframes, SOCPEN has delivered relatively well.
- **Support from SITA.** SITA plays a pivotal role in supporting and maintaining SOCPEN. In fact, SOCPEN is hosted on mainframes held at SITA. Retaining talented staff is a challenge. The government needs to build internal support mechanisms to run MIS system nationally, through a dedicated information and communications technology agency or a strong internal support team.

---

42 This section has been partly informed by discussions with an information technology consultant involved in developing NISIS.
6.3.4.2 National Integrated Social Information System

SOCPEN’s problems have not been addressed by the NISIS, proving how lack of policy coordination and institutional arrangements are at the basis of IT failure, not the other way round. Issues include:

- **Lack of national DSD involvement and ownership** The provincial DSDs are sometimes deeply involved in the War on Poverty. At national level, involvement has been almost non-existent. The NISIS, therefore, is not always seen as relevant.

- **Slow profiling progress** Household profiling is a massive, labour intensive and logistically complex exercise which the War on Poverty or Comprehensive Rural Development Programme were not capable of performing (including because of lack of resources). This was compounded by increasing lack of interest from the Treasury and central government and no coordinating effort by the DSD.

- **Lack of service delivery** Several factors have led to lack of service delivery including: (i) excess focus on household profiling targets at the expense of service delivery; (ii) lack of focus and/or clarity on the services to be prioritised for delivery; (iii) limited coordination capacity and authority on the ground; (iv) close to non-existent coordination models and institutional arrangements; (v) no dedicated resources from line departments meaning programs compete against their department’s internal priorities; (vi) absence of a clear political or legislative mandate necessary to marshal the line departments responsible for service delivery.

CASE STUDIES

CONCLUSIONS

This Module has clearly shown that – when made a priority – programme MISs are a powerful tool to efficiently implement, manage and monitor social protection programmes. Developing an Integrated System for Information Management – that enables the flow and management of information within the Social Protection sector and sometimes beyond – can have further policy and operational advantages:

- **Policy advantages** can include a more equitable approach to distributing resources based on objective and comparable information; increased responsiveness and inclusiveness of interventions (potentially ensuring universal coverage), increased transparency and accountability (and improved ‘image’ of the Social Protection system); increased links to complementary services and sectors, and; increased knowledge on issues around poverty and vulnerability.

- **Operational advantages** can include facilitated oversight of multiple schemes, reporting to policymakers, and ability to model and test policy changes; decreased burden on staff (e.g. less paperwork) and on potential applicants (e.g. streamlined access to services); increased efficiency of delivery by avoiding duplication of efforts, enabling economies of scale, and ensuring better management of error and fraud; and; improved management, for example enabling beneficiaries to transition between schemes as their circumstances change and establishing more effective emergency responses while ensuring improved M&E, planning and coordination at sector and potentially crosssector level.

The extent to which these advantages are achieved greatly depends on the approach to integration selected (developing a Social Registry, Integrated Beneficiary Registry or Virtual Social Registry, see Section 4.2) and the overarching objectives pursued. It is clear that, whereas many stakeholders understand MISs and their registries/databases from an Information Technology (e.g. software and hardware) perspective, they are primarily a policy tool. This has several implications:

- It is essential for Social Protection stakeholders to set the policy, legal and operational framework for the establishment of their MISs or Integrated System for Information.

- In determining the model to set up, developing countries should not (even though it is natural to look to existing examples) be casually seduced by models arising from middle-income countries (e.g. Brazil, South Africa and Indonesia). Instead, the choice must be carefully made in light of country-specific purpose, needs, and context (including existing opportunities and capacity/financial constraints).
The development of a high quality programme MIS – and to a greater extent the development of an Integrated System for Information Management – requires a complex, costly, lengthy and iterative process which requires very high capacity. Risk of failure is high, and not for IT-related reasons. Governments lacking sufficient capacity will need to be advised/guided in the development process, while investing in capacity-development.

When analysing other countries’ strategies to data and information management the focus should not fall on what the system is called, but on the functions it performs - especially where the data is flowing from and to, and what practical implications that has.

7.1 IMPLICATIONS FOR SUB-SAHARAN AFRICA

The implications for Sub-Saharan Africa are extensive, given the importance of country needs and context in determining the ‘right’ solution to data and information management. Six main considerations should be noted.

First of all, from a policy perspective, a wide range of countries in the region are swiftly striving towards the creation of a comprehensive vision of Social Protection policy (in line with the ILO Social Protection Floor Recommendation). This is reflected in country strategy documents and in regional efforts and has already translated into practice – as Table 9 below shows.

Table 9: African countries which have developed or are developing integrated systems for information management in the Social Protection sector

Source: Honorati, Gentilini and Yemtsov (2015) and authors’ integrations

Secondly, countries across Sub-Saharan Africa have great opportunities to adopt leapfrog technology when it comes to setting up MIS solutions. This has already been the case in countries pioneering the use of programme and integrated MISs, addressing challenges unique to the region: for example, biometric identification can overcome traditional difficulties in identifying beneficiaries without appropriate documentation; point-of-sale devices or mobile phones can be used to transfer cash to nomadic or hard-to-reach beneficiaries electronically (allowing for instant integration with MIS); and mobile phones or hand-held devices may be used for data collection (Garcia and Moore, 2012).

Third, capacity constraints will need serious tackling – at central and local level. While the Ministries and Agencies in charge of implementing Social Protection across the region have been strengthening their role and cadre of staff, there is still a significant lack of: a) technical staff at central level, capable of leading the MIS development process while also understanding policy and implementation requirements; b) field-staff at local level (e.g. a cadre of social assistants), capable of acting as liaisons with programme applicants and beneficiaries. Countries that have recently succeeded in their process of data integration, such as Kenya, have undertaken rigorous Capacity Needs Assessments to tackle this issue. They have also adapted their systems to existing capacity constraints, for example by a) gradually building on existing systems rather than adopting a ‘big-bang’ approach; b) outsourcing development tasks to external companies and/or receiving donor technical assistance, and c) adapting business processes to capacity constraints (e.g. impossibility of on-demand data collection in the short term given lack of local staff).

Fourth, the sustainability of any MIS project – and especially a large project involving the creation of an integrated system – is largely reliant on a sustainable source of funding allowing for on-going operations (including training and technical support for staff), maintenance and potential changes/weaknesses. This is problematic in contexts where Social Protection is still struggling to garner sufficient domestic financing – as is often the case in Sub-Saharan Africa (Garcia and Moore, 2012). An MIS project’s Feasibility Study should realistically assess the cost implications of different models of MIS development and rollout, and base ultimate choices on the availability of adequate financing.

Fifth, MIS projects in the region need extensive tailoring to the specific objectives and characteristics of social assistance programs, as extensively described within Garcia and Moore (2012). For example, given most programmes’ strong focus on targeting vulnerable groups rather than ‘the poor’, a unified approach to poverty targeting across different programs could be more difficult to implement. Similarly, given the high level of community involvement in all of the ‘gateway’ phases of programme implementation, any proposed MIS solution would have to find a way to accommodate this.

Sixth, the wider ‘enabling’ (or ‘disabling’) context also needs to be accounted for, possibly at the early design stages (Feasibility Study). From an IT standpoint, the lack of reliable mobile phone, network coverage and electricity, or lack of basic hardware infrastructure could seriously undermine the success of an MIS programme in the region (e.g. rural areas) – especially where one of the core objectives is improved management and coordination across central and decentralised levels of government. From a wider country-context perspective, it is essential to understand whether existing data privacy and security legislation in the region is strong enough to protect already-vulnerable groups from further vulnerability.

The TRANSFORM Learning Package is organized in a modular structure, and reflects the key building blocks of a holistic & interdependent social protection system.

The TRANSFORM modules that are currently available are listed below. Other modules are under development and will be added to the curriculum.

- **LEG** - Legal Frameworks
- **S&I** - Selection & Identification
- **ADM** - Administration and Delivery Systems
- **COO** - Coordination
- **GOV** - Governance, Institutions & Organizational Structure
- **MIS** - Management Information Systems & Approaches to Data Integration
- **FIN** - Financing & Financial Management
- **M&E** - Monitoring & Evaluation

All TRANSFORM materials are available at: [http://socialprotection.org/institutions/transform](http://socialprotection.org/institutions/transform)
WHAT IS TRANSFORM?

TRANSFORM is an innovative learning package on the administration of national social protection floors in Africa. The prime objective of TRANSFORM is to build critical thinking and capacities of policy makers and practitioners at national and decentralized levels to improve the design, effectiveness and efficiency of social protection systems. TRANSFORM aims not only at imparting state-of-the-art knowledge that is appropriate for the challenges faced by countries in the region, but also to encourage learners to take leadership on the change and transformation of nationally defined social protection systems.

WHY TRANSFORM?

Many training curricula exist in the field of social protection and thus fundamental ideas, concepts, approaches and techniques are accessible. And yet, institutions and individuals struggle with the complexity of developing a broad, encompassing social protection system.

This complexity requires a transformational approach to teaching and knowledge sharing. It is far from enough to impart knowledge, to fill heads. It requires learners to grapple with the features of complexity, to stimulate creativity, to appreciate diversity and uniqueness, to be involved as a key element of ownership – elements which are at least as important as the factual knowledge itself. This learning package aims at just that: TRANSFORM!
